

# One way bets on pegged exchange rates

Ila Patnaik    Ajay Shah

September 29, 2008

# Evolution of the Indian exchange rate regime

Structural break dates identified using Zeileis, Patnaik, Shah:

	Dates	INR/USD	Reserves addition (Bln. USD)	
		Weekly vol.	Overall	Per year
1	1993-04 - 1995-02	0.16	13.03	6.93
2	1995-02 - 1998-08	0.93	4.86	1.39
3	1998-08 - 2004-03	<b>0.29</b>	82.64	14.81
4	2004-03 - 2008-02	0.63	178.23	<b>46.40</b>

# The hypothesis

- Pegged exchange rate
  - Low exchange rate volatility
  - Sustained large scale purchases by the central bank
  - Large reserves assure large depreciations will not take place.
- What is a rational CEO to think?

# The hypothesis

- Pegged exchange rate
  - Low exchange rate volatility
  - Sustained large scale purchases by the central bank
  - Large reserves assure large depreciations will not take place.
- What is a rational CEO to think?
- A fair chance of appreciation; a low probability of depreciation; a certainty that large depreciations will not take place.
- A one way bet.

# The hypothesis

- Pegged exchange rate
  - Low exchange rate volatility
  - Sustained large scale purchases by the central bank
  - Large reserves assure large depreciations will not take place.
- What is a rational CEO to think?
- A fair chance of appreciation; a low probability of depreciation; a certainty that large depreciations will not take place.
- A one way bet.
- Firms will modify their exchange rate exposure so as to profit from this exchange rate outlook.

# Measurement of exchange rate exposure

- Accounting data is not useful.
- Stock returns  $r_j$ , broad market index  $r_{M1}$ , exchange rate  $r_{M2}$ , a model:

$$r_j = \alpha + \beta_1 r_{M1} + \beta_2 r_{M2} + \epsilon$$

- $\beta_2$ : Rise in stock price for a 1% currency depreciation.
- Nominal INR/USD appropriate given dollar pegging, and the statistical efficiency gained by using high-frequency data.

## The challenge of estimating $\beta_2$

- Lack of statistical precision in an emerging markets setting, where unsystematic risk is high and exchange rate flexibility is low

## The challenge of estimating $\beta_2$

- Lack of statistical precision in an emerging markets setting, where unsystematic risk is high and exchange rate flexibility is low
- Change in behaviour across changes in the exchange rate regime

## The challenge of estimating $\beta_2$

- Lack of statistical precision in an emerging markets setting, where unsystematic risk is high and exchange rate flexibility is low
- Change in behaviour across changes in the exchange rate regime
- Lags in response

## The challenge of estimating $\beta_2$

- Lack of statistical precision in an emerging markets setting, where unsystematic risk is high and exchange rate flexibility is low
- Change in behaviour across changes in the exchange rate regime
- Lags in response
- Forecastability of the exchange rate given pegging.

## The challenge of estimating $\beta_2$

- Lack of statistical precision in an emerging markets setting, where unsystematic risk is high and exchange rate flexibility is low
- Change in behaviour across changes in the exchange rate regime
- Lags in response
- Forecastability of the exchange rate given pegging.
- If a one-way bet *is* present, exchange rate exposure is in the market index!

We will end up reading how  $\hat{\beta}_2$  differs from the average exposure of the index.

## The challenge of estimating $\beta_2$

- Lack of statistical precision in an emerging markets setting, where unsystematic risk is high and exchange rate flexibility is low
- Change in behaviour across changes in the exchange rate regime
- Lags in response
- Forecastability of the exchange rate given pegging.
- If a one-way bet *is* present, exchange rate exposure is in the market index!  
We will end up reading how  $\hat{\beta}_2$  differs from the average exposure of the index.
- Heteroscedasticity.

# Our estimation strategy

- 1 Work within sub-periods of exchange rate regime
- 2 Switch from  $r_{M2}$  to ARMA innovations
- 3 Purge exchange rate exposure from the market index series.
- 4 SBC-minimising lag structure and HAC standard errors.
- 5 Use daily data in order to maximise statistical precision.
- 6 Obtain statistical precision by focusing on industry indexes and not individual stocks:
  - 1 Reduction of unsystematic risk and thus improvement in precision of estimating  $\beta_{M2}$
  - 2 If and only if a one-way bet is present, exchange rate views of multiple firms in an industry will be homogeneous

# Comparison against literature

By and large, in the literature, exchange rate exposure is generally not found either with stocks or with industry indexes. We conjecture it is because:

- With floating exchange rates, there is no one way bet
- Difficulties of measurement.

# Difficulties of measurement: an example

- As an example, focus on just the 11 top level indexes
- Start from a naive measurement strategy
- One by one, introduce elements of sophisticated measurement
- Picture comes into focus.

# I. Weekly data, no structural breaks

<i>t</i> statistic of $\beta_2$	Number of industry indexes			
	P1	P2	P3	P4
$t \leq -1.96$			0	
$-1.96 < t \leq 1.96$			11	
$1.96 < t$			0	

## II. Weekly data, structural breaks

<i>t</i> statistic of $\beta_2$	Number of industry indexes			
	P1	P2	P3	P4
$t \leq -1.96$	0	0	0	0
$-1.96 < t \leq 1.96$	9	11	11	11
$1.96 < t$	2	0	0	0

### III. Weekly data, structural breaks, **purge** $r_{M1}$

$t$ statistic of $\beta_2$	Number of industry indexes			
	P1	P2	P3	P4
$t \leq -1.96$	0	1	7	4
$-1.96 < t \leq 1.96$	8	10	4	7
$1.96 < t$	3	0	0	0

## V. Daily data, structural breaks, purge $r_{M1}$ , currency innovations

$t$ statistic of $\beta_2$	Number of industry indexes			
	P1	P2	P3	P4
$t \leq -1.96$	0	6	10	10
$-1.96 < t \leq 1.96$	3	5	1	1
$1.96 < t$	8	0	0	0

# Exchange rate exposure of Nifty

	P1	P2	P3	P4
Same day	0.538 (0.8)	<b>-0.283</b> <b>(-2.4)</b>	<b>-1.204</b> <b>(-4.0)</b>	<b>-1.249</b> <b>(-8.1)</b>
Lag 1	1.060 (1.6)	-0.055 (-0.5)	<b>-0.603</b> <b>(-2.0)</b>	<b>-0.398</b> <b>(-2.6)</b>
Lag 2	0.877 (1.3)	0.092 (0.8)	0.002 (0.0)	-0.267 (-1.7)
Lag 3	-0.287 (-0.4)	0.180 (1.5)	-0.342 (-1.1)	0.173 (1.1)
Lag 4	0.656 (0.9)	0.124 (1.0)	0.431 (1.4)	-0.251 (-1.6)
Lag 5	1.008 (1.6)	-0.029 (-0.2)	0.455 (1.5)	-0.119 (-0.8)
$\bar{R}^2$	0.005	0.005	0.015	0.073

# Data for industry indexes

- Family of industry indexes maintained by CMIE
- At the top level, broad industry groups
- A tree of indexes
- We focus on the leaf nodes
- Within each of these narrow industry indexes, natural economic exposure is homogeneous.
- 126 such industry indexes.

## Main result

$t$ statistic of $\beta_2$	Number of industry indexes			
	P1	P2	P3	P4
$t \leq -1.96$	0	29	68	93
$-1.96 < t \leq 1.96$	91	94	57	33
$1.96 < t$	32	1	0	0

Many exporting industries - which should ordinarily gain from depreciation - moved around in this table through time and managed to obtain the opposite exposure.

# Robustness checks

- Choice of market index
- Choice of return interval
- Alternative definition of break dates: Perron-Bai breaks in the time-series of months of import cover.
- The basic results stand.

# Conclusion

- In Period 4, 93 of 126 industry indexes had a bet on appreciation.
- With low volatility, large reserves and sustained one-way purchases by RBI, economic agents appear to have been convinced that there was a one-way bet.
- Capital controls and financial markets were sufficiently conducive for achieving large changes in exchange rate exposure.

Thank you.
