Asymptotic theorems

We will review the two important asymptotic theorems.

- Law of large numbers
- Central Limit Theorem
Law of large numbers

Theorem (Law of large numbers)
If $x_1, \ldots, x_n$ are iid random variables with finite mean $\mu$ and finite variance $\sigma^2$ and $\bar{X}_n = (1/n) \sum_{i=1}^n x_i$, then

$$\bar{X} \xrightarrow{p} \mu$$
Central Limit Theorem

Theorem (Central Limit Theorem)

If \( x_1, \ldots, x_n \) are iid random variables with finite mean \( \mu \) and finite variance \( \sigma^2 \) and \( \bar{X}_n = (1/n) \sum_{i=1}^{n} x_i \), then

\[
\bar{x}_n \xrightarrow{d} N \left( \mu, \frac{\sigma^2}{n} \right)
\]

However this distribution is degenerate: the total mass is around \( \mu \). Usually, we rewrite:

\[
\sqrt{n}(\bar{x}_n - \mu) \xrightarrow{d} N(0, \sigma^2)
\]

4 Implementation in R
Consider the usual regression case:

\[ Y = X\beta + \varepsilon \]

The OLS estimator is given by:

\[ \hat{\beta} = (X'X)^{-1}X'Y \]
Inference

Under hypotheses:

- $X$ and $\varepsilon$ are independent
- $\varepsilon \sim iid(0, \sigma^2 I_n)$ ($\iff$ no heteroskedasticity or autocorrelation)
- $\text{plim} \frac{X'X}{n} = Q$

Proposition

- It is unbiased
- Its variance is given by: $\sigma^2 \varepsilon (X'X)^{-1}$
- It is convergent
- Its asymptotic distribution is normal. $\sqrt{T} (\hat{\beta} - \beta) \xrightarrow{d} N(0, \sigma^2 Q^{-1})$
Under hypotheses:

- $X$ and $\varepsilon$ are independent
- $\varepsilon \sim iid(0, \sigma^2 I_n)$ (⇔ no heteroskedasticity or autocorrelation)
- $\text{plim} \, \frac{X'X}{n} = Q$

Proposition

- It is unbiased
- Its variance is given by: $\sigma^2 \varepsilon (X'X)^{-1}$
- It is convergent
- Its asymptotic distribution is normal: $\sqrt{T} (\hat{\beta} - \beta) \xrightarrow{d} N(0, \sigma^2 Q^{-1})$
Inference

Under hypotheses:

- $X$ and $\varepsilon$ are independent
- $\varepsilon \sim iid(0, \sigma^2 I_n)$ ($\iff$ no heteroskedasticity or autocorrelation)
- $\operatorname{plim} \frac{X'X}{n} = Q$

**Proposition**

- It is unbiased
- Its variance is given by: $\sigma^2_{\varepsilon}(X'X)^{-1}$
- It is convergent
- Its asymptotic distribution is normal. $\sqrt{T}(\hat{\beta} - \beta) \xrightarrow{d} N(0, \sigma^2 Q^{-1})$
Inference

Under hypotheses:

- $X$ and $\varepsilon$ are independent
- $\varepsilon \sim iid(0, \sigma^2 I_n) (\iff$ no heteroskedasticity or autocorrelation $)$
- $\text{plim} \frac{X'X}{n} = Q$

The estimator has following properties:

**Proposition**

- It is unbiased
- Its variance is given by: $\sigma^2_{\varepsilon}(X'X)^{-1}$
- It is convergent
- Its asymptotic distribution is normal. $\sqrt{T}(\hat{\beta} - \beta) \overset{d}{\rightarrow} N(0, \sigma^2 Q^{-1})$
Inference

Under hypotheses:

- $X$ and $\varepsilon$ are independent
- $\varepsilon \sim iid(0, \sigma^2 I_n)$ ($\iff$ no heteroskedasticity or autocorrelation)
- $\plim \frac{X'X}{n} = Q$

The estimator has following properties:

**Proposition**

- *It is unbiased*
  - Its variance is given by: $\sigma^2_{\varepsilon}(X'X)^{-1}$
- It is convergent
- Its asymptotic distribution is normal. $\sqrt{T}(\hat{\beta} - \beta) \xrightarrow{d} N(0, \sigma^2 Q^{-1})$
Inference

Under hypotheses:

- $X$ and $\varepsilon$ are independent
- $\varepsilon \sim iid(0, \sigma^2 I_n)$ ($\Leftrightarrow$ no heteroskedasticity or autocorrelation)
- $\text{plim} \frac{X'X}{n} = Q$

The estimator has following properties:

**Proposition**

- *It is unbiased*
- *Its variance is given by: $\sigma^2(\varepsilon)'(\varepsilon)N^{-1}$*
- *It is convergent*
- *Its asymptotic distribution is normal. $\sqrt{T}(\hat{\beta} - \beta) \xrightarrow{d} N(0, \sigma^2 Q^{-1})$*
Inference

Under hypotheses:
- \( X \) and \( \varepsilon \) are independent
- \( \varepsilon \sim iid(0, \sigma^2 I_n) (\iff \text{no heteroskedasticity or autocorrelation}) \)
- \( \text{plim } \frac{X'X}{n} = Q \)

The estimator has following properties:

**Proposition**
- *It is unbiased*
- *Its variance is given by: \( \sigma^2_\varepsilon (X'X)^{-1} \)*
- *It is convergent*
- *Its asymptotic distribution is normal. \( \sqrt{T}(\hat{\beta} - \beta) \xrightarrow{d} N(0, \sigma^2 Q^{-1}) \)*
Inference

Under hypotheses:

- $X$ and $\varepsilon$ are independent
- $\varepsilon \sim iid(0, \sigma^2 I_n)$ ($\Leftrightarrow$ no heteroskedasticity or autocorrelation)
- $\text{plim} \frac{X'X}{n} = Q$

The estimator has following properties:

**Proposition**

- *It is unbiased*
- *Its variance is given by:* $\sigma^2_\varepsilon (X'X)^{-1}$
- *It is convergent*
- *Its asymptotic distribution is normal.* $\sqrt{T}(\hat{\beta} - \beta) \xrightarrow{d} N(0, \sigma^2 Q^{-1})$
To study the properties of the OLS estimator, we will start from:

**Proposition**

\[ \hat{\beta} = \beta + (X'X)^{-1}X'\varepsilon \]

**Proof.**

\[
\hat{\beta} = (X'X)^{-1}X'Y \\
= (X'X)^{-1}X'(X\beta + \varepsilon) \\
= (X'X)^{-1}X'X\beta + (X'X)^{-1}X'\varepsilon \\
= \beta + (X'X)^{-1}X'\varepsilon
\]
The OLS estimator is unbiased: $\mathbb{E}(\hat{\beta}) = \beta$

Proof.

$$
\mathbb{E}[\hat{\beta}] = \mathbb{E} \left[ \beta + (X'X)^{-1}X'\varepsilon \right] \\
= \beta + (X'X)^{-1}X'\mathbb{E}[\varepsilon] \quad \text{if } X \text{ and } \varepsilon \text{ independent} \\
= \beta \quad \text{if } \mathbb{E}[\varepsilon] = 0
$$
Proposition

The variance of the OLS estimator is: \( \text{Var}[\hat{\beta}] = \sigma^2_\varepsilon (X'X)^{-1} \)

Proof.

\[
\begin{align*}
\text{Var}[\hat{\beta}] &= \text{Var} \left[ \beta + (X'X)^{-1} X' \varepsilon \right] \\
&= (X'X)^{-1} X' \text{Var}[\varepsilon] X (X'X)^{-1} \\
&= (X'X)^{-1} X' \sigma^2_\varepsilon I_n X (X'X)^{-1} \quad \text{if } \text{Var}[\varepsilon] = \sigma^2 I_n \\
&= \sigma^2 \left( X'X \right)^{-1} X' X (X'X)^{-1} \\
&= \sigma^2_\varepsilon (X'X)^{-1}
\end{align*}
\]
Convergence of the OLS

Proposition

The OLS estimator is convergent: $\hat{\beta} \xrightarrow{p} \beta$

Proof.

From:

$$\hat{\beta} = \beta + (X'X)^{-1}X'\varepsilon$$

$\hat{\beta}$ can be rewritten as:

$$\hat{\beta} = \beta + \left( \frac{(X'X)}{T} \right)^{-1} \frac{X'\varepsilon}{T}$$

We will see that:

$$\left( \frac{(X'X)}{T} \right)^{-1} \xrightarrow{p} Q^{-1}$$

$$\frac{X'\varepsilon}{T} \xrightarrow{p} 0$$
First element: we make the assumption that: \( \lim_{n \to \infty} \frac{X'X}{n} = Q \), hence
\[
\left( \frac{X'X}{T} \right)^{-1} \Rightarrow Q^{-1}
\]
Second element: \( \left( \frac{X'\varepsilon}{T} \right) \)
- \( E[X' \varepsilon] = 0 \) under the assumptions:
  - \( X \) and \( \varepsilon \) independent
  - \( E[\varepsilon] = 0 \)
- \( \text{Var}[\frac{X'\varepsilon}{T}] = \frac{X' \text{Var}[\varepsilon] X}{T} = \frac{\sigma^2}{T} \frac{X'X}{T} = \frac{\sigma^2}{T} Q \to 0 \)

We have hence: \( \text{plim} \ \frac{X'\varepsilon}{T} \to 0 \)

Finally, we see that:

**Proposition**

\[
\text{plim} \ \hat{\beta} = \beta + Q^{-1}0 = \beta \Rightarrow \hat{\beta} \xrightarrow{p} \beta
\]
Distribution of the OLS

- Finite sample: if $\varepsilon_i \sim \mathcal{N}()$ the OLS is normally distributed
- Asymptotic: OLS is normally distributed by a TCL

**Proposition**

$$\sqrt{n}(\hat{\beta} - \beta) \xrightarrow{L} \mathcal{N}(0, \sigma^2 Q^{-1})$$
Distribution of the OLS: proof

\[ \hat{\beta} = \beta + \left( \frac{(X'X)}{n} \right)^{-1} \frac{X' \varepsilon}{n} \rightarrow \sqrt{n}(\hat{\beta} - \beta) = \left( \frac{(X'X)^{-1}}{n} \right) \sqrt{n} \frac{X' \varepsilon}{n} \]

If:
- X and \( \varepsilon \) are independent
- \( E(X\varepsilon) = 0 \)

Define new variable \( w = x_i \varepsilon_i \)

We have \( \bar{w} = \frac{X' \varepsilon}{n} = \frac{1}{n} \sum_{i=1}^{n} x_i \varepsilon_i \)

- Is iid
- Has expectation 0
- Has variance \( \frac{\sigma^2}{n} Q \)

Hence by a TCL (Lindberg-Feller):

\[ \sqrt{n}(\bar{w} - E(\bar{w})) \xrightarrow{L} \mathcal{N}(0, \sigma^2 Q) \]

**Proposition**

\[ \sqrt{n}(\hat{\beta} - \beta) \xrightarrow{L} \mathcal{N}(Q^{-1}0, Q^{-1} \sigma^2 QQ^{-1}) = \mathcal{N}(0, \sigma^2 Q^{-1}) \]
Review of the assumptions

We had to make the following assumptions:

- $X$ and $\varepsilon$ are independent
- $\varepsilon \sim iid(0, \sigma^2 I_n)$ ($\Leftrightarrow$ no heteroskedasticity or autocorrelation)
- $\lim_{n \to \infty} \frac{X'X}{n} = Q$

Do these assumptions hold for correlated data? (no more independent!)
Review of the assumptions

We had to make the following assumptions:

- $X$ and $\varepsilon$ are independent
- $\varepsilon \sim iid(0, \sigma^2 I_n)$ ($\iff$ no heteroskedasticity or autocorrelation)
- $\lim_{n \to \infty} \frac{X'X}{n} = Q$

Do these assumptions hold for correlated data? (no more independent!)
Review of the assumptions

We had to make the following assumptions:

- $X$ and $\varepsilon$ are independent
- $\varepsilon \sim iid(0, \sigma^2 I_n)$ ($\iff$ no heteroskedasticity or autocorrelation)
- $\lim_{n \to \infty} \frac{X'X}{n} = Q$

Do these assumptions hold for correlated data? (no more independent!)
The assumption that $\text{plim} \frac{X'X}{n} = Q$ relies on a law of large numbers.

\[
X'X = \sum_{t=1}^{T} x_t x_t' = \sum_{t=1}^{T} \begin{pmatrix} 1 \\ x_{1t} \\ x_{2t} \\ \vdots \\ x_{kt} \end{pmatrix} \begin{pmatrix} 1 & x_{1t} & x_{2t} & \ldots & x_{kt} \end{pmatrix}
\]
Theoretical moment matrix

\[ Q \equiv E[X'X] = \begin{pmatrix}
1 & \mu_1 & \mu_2 & \cdots & \mu_k \\
\mu_1 & \sigma_1^2 + \mu_1^2 & \sigma_{12} + \mu_1\mu_2 & \cdots & \sigma_{1k} + \mu_1\mu_k \\
\mu_2 & \sigma_{21} + \mu_2\mu_1 & \sigma_2^2 + \mu_2^2 & \cdots & \sigma_{2k} + \mu_2\mu_k \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
\mu_2 & \sigma_{k1} + \mu_k\mu_1 & \cdots & \cdots & \sigma_k^2 + \mu_k^2
\end{pmatrix} \]

This matrix entails:

- First row or columns: Expectations of the variables
- In the diagonal: second moments (equal to the variance if \( E[x_i] = 0 \))
- Elsewhere: second “cross-moments” (equal to the covariance if \( E[x_i] = E[x_j] = 0 \))
Empirical moment matrix

\[ X'X = \begin{pmatrix} T & \sum x_{1i} & \sum x_{2i} & \ldots & \sum x_{ki} \\ \sum x_{2i} & \sum x_{2i}^2 & \sum x_{2i}x_{3i} & \ldots & \sum x_{2i}x_{ki} \\ \sum x_{3i} & \sum x_{3i}x_{2i} & \sum x_{3i}^2 & \ldots & \sum x_{3i}x_{ki} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \sum x_{ki} & \sum x_{ki}x_{2i} & \sum x_{ki}x_{3i} & \ldots & \sum x_{ki}^2 \end{pmatrix} \]
Convergence of the empirical moment matrix

Theorem

\[ \frac{X'X}{T} \overset{p}{\to} Q \]

This convergence is proved by the law of large numbers:

- \((1/n) \sum_{i=1}^{n} x_i \overset{p}{\to} E[x] = \mu\)
- \((1/n) \sum_{i=1}^{n} x_i^2 \overset{p}{\to} E[x^2] = \mu^2 + \sigma^2\)
- \((1/n) \sum_{i=1}^{n} x_1 x_2i \overset{p}{\to} E[x_1 x_2] = \mu_1 \mu_2 + \sigma_{12}\)

When we use the fact that (Greene, p. 900, 5 ed):

Proposition

\[(1/n) \sum_{i=1}^{n} g(x_i) \overset{p}{\to} E[g(x)] \text{ if a LLN hold for } x\]
1 Standard theory
   - Asymptotic theorems
   - The linear regression

2 Correlated data

3 The random walk
   - Distribution problems
   - Discussion of others tests
   - Stationarity tests

4 Implementation in R
Process with autocorrelation

Consider the usual AR(1) process:

\[ Y_t = \varphi Y_{t-1} + \varepsilon_t \]

The OLS estimator is given by:

\[ \hat{\varphi}_T = \frac{\sum_{i=2}^{T} Y_t Y_{t-1}}{\sum_{i=2}^{T} Y_{t-1}^2} \]

It has properties:

- **Biased** since the assumption that the regressors and the disturbances are independent is no more valid.
- **Consistent** by a law of large numbers for correlated data
- **Normally distributed**

Its asymptotic distribution is:

\[ \sqrt{T}(\hat{\varphi} - \varphi) \xrightarrow{d} N(0, 1 - \varphi^2) \]
Extensions of law of large numbers and TCL

Proposition (Law of large numbers for correlated process)

If $Y_t$ is a stationary process with MA coefficients $\sum_{j=0}^{\infty} |\gamma_j| < \infty$, then

$$\bar{Y}_t \overset{p}{\to} \mu$$

Proposition (TCL for martingale difference sequence)

$$\frac{1}{\sqrt{T}} \sum_{i=1}^{T} \varepsilon_t Y_{t-k} \overset{L}{\to} \mathcal{N}(0, \sigma^2 \text{E}(Y_t^2))$$

So from: $\hat{\varphi}_T = \phi + \frac{\sum_{i=2}^{T} Y_{t-1}\varepsilon_t}{\sum_{i=2}^{T} Y_{t-1}^2}$

- $\sum_{i=2}^{T} Y_{t-1}^2 \overset{p}{\to} Q^{-1}$
- $\sum_{i=2}^{T} Y_{t-1}\varepsilon_t \overset{p}{\to} 0$
- $\sqrt{T} \sum_{i=2}^{T} Y_{t-1}\varepsilon_t \overset{L}{\to} \mathcal{N}(0, \sigma^2 Q)$

Matthieu Stigler Matthieu.Stigler at gmail.com
Nonstationarity

Covariance matrix estimation

\[
\text{Var}[\hat{\beta}] = \text{Var} \left[ \beta + (X'X)^{-1}X'\varepsilon \right] \\
= (X'X)^{-1}X' \text{Var}[\varepsilon] X(X'X)^{-1} \\
= (X'X)^{-1}X' \Omega_\varepsilon X(X'X)^{-1}
\]

So we wish to estimate: \(X' \Omega_\varepsilon X\)

- White estimation (HC): \(S_0 = \frac{1}{n} \sum \hat{\varepsilon}_i x_i x_i'\)
- Newey West (HAC): \(S_0 + \frac{1}{n} \sum_{l}^{L} \sum_{l+1}^{n} w_l e_t e_{t-l}(x_t x_{t-l} + x_{t-l} x_t')\)
Outline

1. Standard theory

   - Stationarity tests

4. Implementation in R
Random walk

Recall the distribution of a AR(1) process:

\[ \sqrt{T}(\hat{\phi} - \varphi) \xrightarrow{d} N(0, 1 - \varphi^2) \]

What happens if \( \phi = 1 \)? Zero variance? Degenerate distribution!

\[ \sqrt{T}(\hat{\phi} - 1) \xrightarrow{p} 0 \]

**Definition (rate of convergence)**

The rate of convergence of an estimator corresponds to the normalisation needed to ensure that it is non-degenerate.

**Proposition**

The usual rate of convergence of estimator is \( \sqrt{n} \) (mean, OLS usual coefficients).

**Proposition**

The OLS estimator converge at rate \( T \) when \( \phi = 1 \). It is said super-convergent.
> distrho1 <- function(n) {

phi=0.8

N = 10000   Bandwidth = 0.06478

Density
Some intuition about the rate of convergence

See that each $Y_t = Y_0 + \varepsilon_1 + \varepsilon_2 + \ldots + \varepsilon_t \sim \mathcal{N}(0, t\sigma^2)$

The mean is:

$$\frac{1}{T} \sum_{i=1}^{T} Y_i = \underbrace{Y_1}_{\varepsilon_1} + \underbrace{Y_2}_{\varepsilon_1 + \varepsilon_2} + \ldots + \underbrace{Y_T}_{\varepsilon_1 + \ldots + \varepsilon_T}$$

$$= T\varepsilon_1 + (T-1)\varepsilon_2 + \ldots + \varepsilon_T$$

The variance of the mean is:

$$\text{Var}\left(\frac{1}{T} \sum_{i=1}^{T} Y_i\right) = \frac{1}{T^2} \sum_{t=1}^{T} t^2 \sigma^2 = \frac{T(T+1)(2T+1)}{6} \sigma^2 \approx \frac{2T \sigma^2}{6}$$

Remember:

- $\sum_{1}^{T} t = \frac{T(T+1)}{2}$
- $\sum_{1}^{T} t^2 = \frac{T(T+1)(2T+1)}{6}$

So we need to normalise by $\sqrt{T}$ to obtain a stable form:

$$\frac{1}{\sqrt{T}} \bar{Y} \sim \mathcal{N}(0, \frac{1}{3} \sigma^2)$$
Distribution of $\hat{\phi}$

We need to study $T(\hat{\phi} - 1) = \frac{T^{-1} \sum_{t=2}^{T} Y_t Y_{t-1}}{T^{-2} \sum_{t=2}^{T} Y_{t-1}^2}$

So we find something like:

$$T(\hat{\phi} - 1) \buildrel L \over \to \frac{1/2}{\int_{0}^{1} [W(r)]^2 dr} \{ [W(1)]^2 - \frac{\sigma_y^2}{\sigma^2} \}$$

**Definition**

$W(r)$ is a Brownian Motion. It is normally distributed, with independent variations which are also normally distributed.
So when the true DGP is:

\[ Y_t = Y_{t-1} + \varepsilon_t \]

And we estimate it by

\[ Y_t = \phi Y_{t-1} + \varepsilon_t \]

We have the first Dickey-Fuller tests:

- \( T(\hat{\phi} - 1) \)
- \( t_T = \frac{\hat{\phi} - 1}{\hat{\sigma}_\hat{\phi}} \)

These both tests have non-standard distributions, so critical values are needed.
Critical values finding

> tstat <- function(n) {
+   u <- rnorm(n)
+   y <- cumsum(c(0, u))
+   ylags <- embed(y, 2)
+   reg <- lm(ylags[, 1] ~ ylags[, 2] - 1)
+   tstat <- (coef(reg) - 1)/coef(summary(reg))[, "Std. Error"]
+   arstat <- n * (coef(reg) - 1)
+   return(c(tstat, arstat))
+ }
> MC <- replicate(10000, tstat(25))
For the case \( n = 25 \) you find the tables:

\[
\begin{array}{cccccccc}
T(\hat{\phi} - 1) & 0.01 & 0.025 & 0.05 & 0.10 & \ldots & 0.90 & 0.95 & 0.975 & 0.99 \\
\hline
-11.9 & -9.3 & -7.3 & -5.3 & \ldots & 1.01 & 1.4 & 1.79 & 2.28 \\
tT = \frac{\hat{\phi} - 1}{\hat{\sigma}^2} & -2.66 & -2.26 & -1.95 & -1.6 & \ldots & 0.92 & 1.33 & 1.7 & 2.16 \\
\end{array}
\]
> plot(density(MC[1, ]), col = 2)
> lines(curve(dt(x, df = 25), n = 100, from = -3, to = 3, add = TRUE))
> legend("topleft", lty = 1, col = c(1, 2), legend = c("Usual t-stat", + "DF t-stat"))
Generalisation to correlated errors

We saw the distribution of the $\hat{\phi}$ test to be:

$$T(\hat{\phi} - 1) \xrightarrow{L} \frac{(1/2)\{[W(1)]^2 - 1\}}{\int_0^1 [W(r)]^2 dr}$$

But this is with iid errors, more generally it is:

$$T(\hat{\phi} - 1) \xrightarrow{L} \frac{(1/2)\{[W(1)]^2 - \frac{\sigma_u^2}{\sigma^2}\}}{\int_0^1 [W(r)]^2 dr}$$

Where:

- $\sigma_u^2 = \lim_{T \to \infty} T^{-1} \sum_{t=1}^T E(\varepsilon_t^2)$ Variance of $\varepsilon$
- $\sigma^2 = \lim_{T \to \infty} T^{-1} E(\sum_{t=1}^T \varepsilon_t)^2$

**Proposition**

*If the errors are iid, $\sigma_u^2 = \sigma^2$*

How to take into account this serial correlation?

- Obtain model with no correlation: augmented Dickey-Fuller (ADF)
- Correct the estimator to take into account the correlation: Philips

Matthieu Stigler
Matthieu.Stigler at gmail.com
Nonstationarity
January 9, 2009 38 / 70
ADF test

Data is generated by an AR(p) process:

$$(1 - \phi_1 L - \phi_2 L^2 - \ldots - \phi_p L^p) y_t = \varepsilon_t$$

And so we have:

$$y_t = \phi_1 y_{t-1} + \phi_2 y_{t-2} + \ldots + \phi_p y_{t-p} + \varepsilon_t$$

It can be rewritten (Beveridge and Nelson):

$$y_t = \rho y_{t-1} + \zeta_1 \Delta y_{t-1} + \zeta_2 \Delta y_{t-2} + \ldots + \zeta_{p-1} \Delta y_{t-p-1} + \varepsilon_t$$

with $\rho = \phi_1 + \phi_2 + \ldots + \phi_p$

If there is one unit root: $\iff z = 1$ in $1 - \phi_1 z - \phi_2 z^2 - \ldots - \phi_p z^p = 0$

So $\rho = 1$
Furthermore we have the results:

**Proposition**

\[
\frac{T(\hat{\rho} - 1)}{1 - \hat{\zeta}_1 - \hat{\zeta}_2 - \ldots - \hat{\zeta}_{p-1}} \text{ has the same DF distribution as in the iid case.}
\]

**Proposition**

*The t-stat has the same DF distribution as in the iid case.*

**Proposition**

*The \( \hat{\zeta}_i \) have the usual Normal distribution, and hence t and F-test can be conducted in the normal way.*
The PP test

Philips and Perron (1988) correct the AR(1) regression for serial correlation:

\[ \hat{\phi} \text{ stat : } T(\hat{\phi} - 1) - \frac{\hat{\sigma}^2 - \hat{\sigma}_u^2}{T^{-2} \sum y_{t-1}^2} \]

- \( \hat{\sigma}_u^2 = T^{-1} \sum (y_t - y_{t-1})^2 \)
- \( \hat{\sigma}^2 = T^{-1} \sum u^2 + 2 T^{-1} \sum_{i=1}^l w_i \gamma_i \)
- \( w_i \) is a weight-kernel function (Bartlett kernel as in Newey West )

Proposition

The PP correction \( \hat{\phi} \) for non iid errors has the same distribution as the \( \hat{\phi} \) with iid errors.
We have seen two types of tests:

- ADF: add lags in the regression (choice of p?)
- PP: correct the test for correlation (choice of kernel? of bandwidth?)

Both tests have two variants: t-test and $\phi$ test.

**Proposition**

*The PP and ADF versions of the t-test and $\phi$ test have the same non-standard distribution, as in the iid case.*
Random-walk estimated with drift

So when the true DGP is:

\[ Y_t = Y_{t-1} + \varepsilon_t \]

We saw the distribution of the estimator of \( \phi \) and of the t-test from:

\[ Y_t = \phi Y_{t-1} + \varepsilon_t \]

But what if we estimate it by:

\[ Y_t = \alpha + \phi Y_{t-1} + \varepsilon_t \]

Complications...

The distribution of \( \phi \) is different, that of the t-test also, and \( \alpha \) has non-standard distribution.

Definition (Nuisance parameter)

The \( \alpha \) parameter is called nuisance parameter: its presence modifies the form of the distribution of \( \phi \)
Case 2

We have now three hypothesis:

- $H_0 : \phi = 1$
  - DF with iid or ADF: t-test/Coefficient test
  - PP test: t-test/Coefficient test
- $H_0 : \hat{\alpha} = 0$ (not much used... PP version?)
- $H_0 : \hat{\alpha} = 0 \cap \phi = 1$

So we need four tabulated distributions:

- For t-tests
- For coefficient tests
- For $t_\alpha$
- For joint hypothesis
True DGP is:

\[ Y_t = \alpha + Y_{t-1} + \varepsilon_t \]

Estimated regression:

\[ Y_t = \hat{\alpha} + \hat{\phi} Y_{t-1} + \varepsilon_t \]

But we have this time:

**Proposition**

\[
\begin{bmatrix}
    T^{1/2}(\hat{\alpha} - \alpha) \\
    T^{3/2}(\hat{\phi} - 1)
\end{bmatrix} \xrightarrow{L} \mathcal{N}(0, \sigma^2 Q^{-1})
\]
Case 3: explanation

Rewrite $Y_t = \alpha + Y_{t-1} + \varepsilon_t$:

$$y_t = y_0 + \alpha t + (u_1 + u_2 + \ldots + u_t)$$

Study the sum:

$$\sum_{i=1}^{T} y_{t-1} = \sum_{i=1}^{T} y_0 + \sum_{i=1}^{T} \alpha(t-1) + \sum_{i=1}^{T} \sum_{i=1}^{T} u_i$$

*The regressor $y_{t-1}$ is asymptotically dominated by the time trend $\alpha(t-1)$. In large samples, it is as if the variable $y_{t-1}$ were replaced by the time trend $\alpha(t-1)$. (Hamilton 1994, p 497)*
Case 4

True DGP is:

\[ Y_t = \alpha + Y_{t-1} + \varepsilon_t \]

Estimated regression:

\[ Y_t = \hat{\alpha} + \hat{\beta}t + \hat{\phi}Y_{t-1} + \varepsilon_t \]

Complications...

The distribution of \( \phi \) is different, that of the t-test also, \( \alpha \) and \( \beta \) have non-standard distribution.
Case 4

We have many hypotheses:

- \( H_0 : \hat{\phi} = 1 \)
  - DF with iid or ADF: t-test/Coefficient test
  - PP test: t-test/Coefficient test
- \( H_0 : \hat{\alpha} = 0 \) (not so used)
- \( H_0 : \hat{\beta} = 0 \) (not so used)
- \( H_0 : \hat{\alpha} = 0 \cap \phi = 1 \) (not so used)
- \( H_0 : \hat{\beta} = 0 \cap \hat{\phi} = 1 \) DF or ADF test

So we need for tabulated distributions:

- For t-tests (case 4)
- For coefficient tests (case 4)
- For joint hypothesis
Case 5

Case 5 is not in Hamilton 1994 (but see Pfaff 2007)

True DGP is:
\[ Y_t = \alpha + \beta t + Y_{t-1} + \varepsilon_t \]

Estimated regression:
\[ Y_t = \hat{\alpha} + \hat{\beta} t + \hat{\phi} Y_{t-1} + \varepsilon_t \]

Proposition

The distribution of the parameters is normal

Again, the deterministic trend dominates the stochastic one.
Interpretation of parameters

Interpretation

The interpretation/effect of the parameters is different under $H_0$ and $H_1$!

Take case 3: True DGP is:

$$Y_t = \alpha + Y_{t-1} + \varepsilon_t$$

Estimated regression:

$$Y_t = \hat{\alpha} + \hat{\phi} Y_{t-1} + \varepsilon_t$$

$\alpha$ is:

- Under $H_0$: a trend parameter ($Y_t = at + Y_0 + \sum_{i=0}^{t-1} \varepsilon_{t-i}$)
- Under $H_1$ a level parameter
  ($Y_t = \frac{a}{1-\varphi} + b \sum_{i=0}^{t-1} \varphi^i (t - i) + \sum_{i=0}^{t-1} \varphi^i \varepsilon_{t-i}$)
Size and power problem

Recall:

**Definition**

Size of a test The *nominal* size of a test is the theoretical probability to reject (take as false) a true event (should not).

This is the $\alpha$ error, fixed at 5%, 10%...
However the empirical size can be higher than observed!
Size with a pure RW process

```r
> library(urca)
> ur.rw <- function(n = 100) {
+   a <- cumsum(c(0, rnorm(n)))
+   ur.df(a)@teststat
+ }
> rep <- replicate(1000, ur.rw())
> mean(ifelse(rep < -1.6, 1, 0))

[1] 0.109
```
Size with a an ARIMA(0,1,1)

```r
> ur.IMA <- function(n, a, test = ur.df) {
+   e <- rnorm(n)
+   pr <- (1 + a) * cumsum(e) - a * e[n]
+   test(pr)@teststat
+ }
> rep2 <- replicate(1000, ur.IMA(100, a = 0.3))
> mean(ifelse(rep2 < -1.6, 1, 0))

[1] 0.107

> rep3 <- replicate(1000, ur.IMA(100, a = -0.9))
> mean(ifelse(rep3 < -1.6, 1, 0))

[1] 0.108

> rep4 <- replicate(1000, ur.IMA(100, a = 1.2, test = ur.pp))
> mean(ifelse(rep4 < -1.6, 1, 0))

[1] 0.817
```
Power of the tests

```r
> ur.ar <- function(n, ar) {
+   ar <- arima.sim(model = list(model = c(1, 0, 0), ar = ar),
+                  n = n)
+   ur.df(ar)@teststat
+ }
> rep5 <- replicate(1000, ur.ar(100, 0.99))
> mean(ifelse(rep5 < -1.6, 1, 0))

[1] 0.224

> rep6 <- replicate(1000, ur.ar(100, 0.9))
> mean(ifelse(rep6 < -1.6, 1, 0))

[1] 0.923
```
Choice of the lag order

ADF test requires choosing p.
Recall that

**Proposition**

The \( \hat{\zeta} \) have the usual Normal distribution, and hence t and F-test can be conducted in the normal way.

- Sequential t-test procedure
- Information based rule: AIC, BIC
- Some rule: \( k = \left[ c \left( \frac{T}{100} \right)^{1/d} \right] \)

Observations show:
- AIC BIC choose too much
ERS test

DF-GLS test:
- Stock (1994) showed that there is no uniformly more powerful test.
- Obtain power envelope by Neyman-Pearson lemma: no test can be better, for fixed $\alpha$ error, than this envelope.
- See that in case without constant or trend, usual tests reach this bound
- In cases with mean and trend, tests are far below
- Conclusion: detrend the data (with GLS) and apply then ADF t-test.

P-test:
Other procedure but gives almost same results as DF-GLS.
ERS power envelope with $c = T(\phi - 1)$

   c. Stationarity tests

4. Implementation in R
KPSS test

KPSS (1992): $H_0$ is stationarity

- Level stationarity $I(0)$
- Trend stationarity not $I(0)$ but not $I(1)$!

$$y_t = \alpha t + r_t + \varepsilon_t$$

Parameter constancy:

$$r_t = r_{t-1} + u_t$$

$H_0$: $\text{Var}(u) = 0$ so $r$ is a constant $\Rightarrow y_t$ is stationary in level/trend
KPSS 2

LM test statistic:

\[ \sum_{t=1}^{T} \left( \sum_{i=1}^{t} \varepsilon_i \right)^2 \hat{\sigma}_{\varepsilon}^2 \]

With iid errors: Take simple estimator of the variance of \( \varepsilon \)

With non iid errors: \( \sigma_{\varepsilon}^2 \) is estimated as in PP test:

\[ \tilde{\sigma}_{\varepsilon}^2 = T^{-1} \sum u^2 + 2 T^{-1} \sum_{i=1}^{l} w_i \gamma_i \]

and the kernel/weight function is the Bartlett window: \( w(l, s) = 1 - \frac{s}{l+1} \)
Simulation show:

- Considerable size distortion when the errors follow AR(1)
- Power is very low when \( l \) is big (12)
- Increasing \( l \) decreases power
Nelson and Plosser (1982) study

Nelson and Plosser (1982) investigate 14 time series:

- Real GNP
- Nominal GNP
- Real Per Capita GNP
- Industrial Production Index
- Total Employment
- Total Unemployment Rate
- GNP Deflator
- Consumer Price Index
- Nominal Wages
- Real Wages
- Money Stock (M2)
- Velocity of money
- Bond Yield (30-year corporate bonds)
- Stock Prices

Nonstationarity

January 9, 2009 66 / 70
Results of the test of Trend stationary vs Difference stationary:

**NP Results**

13 series can be viewed as DS, one (unemployment) as TS.

**KPSS results**

- 1 series is level stationary
- 4 series are I(1): reject stationarity (at every $l = 1 \ldots 8$ and don’t reject unit root
- 3 series seem to be I(1) (result depends on $l$)
- 6 series: can’t reject either the unit root or the trend stationnary $H_0$, the conclusion is that the data are not sufficiently informative.

**Choose want you want**

For 10 series, the result can be interpreted as I(1) or stationary around trend... up to you!
Outline

1. Standard theory
   - Asymptotic theorems
   - The linear regression

3. The random walk
   - Distribution problems
   - Discussion of others tests
   - Stationarity tests

4. Implementation in R
Packages

**Urca**  ADF, PP, ERS, KPSS

**fUnitRoots**  ADF with McKinnon (1996) critical values

**uroot**  ADF (with AIC, BIC, t-stat procedure), seasonal unit roots: HEGY and Hansen & Canova

Missing: Ng & Perron Test, which seems to have good size and high power.
Running this sweave+beamer file

To run this Rnw file you will need:

- Package urca
- ERS.png and table.pdf in file Datasets
- lect4UnitRoot-002.eps/pdf and lect4UnitRoot-002.eps/pdf in Datasets. Those can be actually run from the code but have been saved to avoid too many computations every time.
- (Optional) File Sweave.sty which change output style: result is in blue, R commands are smaller. Also in same folder as .Rnw file.
